Rotational Kinetic Energy and Momentum Problems

1. Four objects - a hoop, a solid cylinder, a solid sphere and a hollow sphere - each have a mass of 4.8 kg and a radius of 0.23 m.
   a. Find the moment of inertia for each object as it rotates about its central axis.

   \[
   I_{\text{hoop}} = \frac{1}{2} m R^2 = 0.2582 \quad \text{kg m}^2 \\
   I_{\text{solid cyl}} = \frac{1}{2} m R^2 = 0.12696 \quad \text{kg m}^2 \\
   I_{\text{solid sphere}} = \frac{2}{5} m R^2 = 0.1023 \quad \text{kg m}^2 \\
   I_{\text{hollow sphere}} = \frac{2}{3} m R^2 = 0.1683 \quad \text{kg m}^2
   \]

   b. Suppose each object rolled down a ramp. Rank the translational speed of each object from the highest to lowest.

   solid sphere, solid cyl, hollow sphere, hoop

   c. Rank the objects' rotational kinetic energies from highest to lowest as the objects hit the bottom of the ramp.

   solid sphere, solid cyl, hollow sphere, hoop

2. A 25 kg hollow sphere 0.2 m in radius rolls without slipping 6.0 m down a ramp that is inclined at 37°. What is the angular speed of the sphere at the bottom of the slope if it starts from rest? (6.52 m/s)

   \[
   \omega = \sqrt{\frac{3g}{2R}} = \sqrt{\frac{6.9 \times 6}{0.4}} = 32.6 \text{ rad/s}
   \]

3. The six figures below show spheres (not drawn to scale) that are about to roll up inclines without slipping. The spheres all have the same mass, but their radii, and linear and angular speeds at the bottom of the incline vary. Specific values are given in the figures for the linear and angular speeds at the bottom.

   Rank these systems on the basis of the maximum height reached on the incline by each sphere.

   Greatest 1 \( \frac{A}{F} \) 3 \( \frac{C}{B} \) 5 \( \frac{D}{C} \) 6 \( \frac{A}{E} \) Least

   Please explain your reasoning.
4. The top shown on the right has a moment of inertia of 0.0004 kgm² and is initially at rest. A force of 5.57 N is applied along the string. If the string does not slip while wound around the peg, what is the angular speed (in rpm) of the top after 80 cm of the string has been pulled off the peg? (Hint: think about energy)

\[ \omega = 149.3 \text{ rad/s} \]

\[ \omega = 7 (9.58 \text{ rpm}) \]

\[ \sqrt{\frac{2F \omega x}{I}} = \sqrt{\frac{2(5.57 \text{ N})(149.3 \text{ rad/s})}{0.0004 \text{ kgm²}}} = \sqrt{\frac{2(5.57 \text{ N})(149.3 \text{ rad/s})}{0.0004 \text{ kgm²}}} \]

\[ \omega = 1425 \text{ rpm} \]

5. There is a comet called 45P that is passed close to us last year. As the comet passes through our solar system, the closest it gets is 0.5326 AU and the furthest from the sun it gets is 5.5167 AU (an AU is the average distance from the Earth to the Sun). If the comet goes about 54 km/s at its closest to the sun, how fast does it go when it is furthest from the sun? (think about L) (5.213 km/s)

\[ L_i = L_f \]

\[ J_i \omega_i = J_f \omega_f \]

\[ T_i r_i^2 \omega_i = T_f r_f^2 \omega_f \]

\[ r_i(u_i) = r_f(u_f) \]

\[ r_i = 0.5326 \text{ AU} \]

\[ r_f = 5.5167 \text{ AU} \]

\[ \omega_f = 5.213 \text{ km/s} \]

6. The mass of the Earth is 6E24 kg, the radius is 6.4E6 m and is 1.5E8 km from the Sun. Determine the angular momentum of the Earth

a. About its rotational axis (assume the Earth is a uniform sphere)

\[ I = \frac{2}{5}mr^2 \]

\[ I = \frac{2}{5}(6.7 \times 10^{24} \text{ kg})(6.4 \times 10^6 \text{ m})^2 = 9.87 \times 10^{33} \text{ kgm}^2 \]

\[ \omega = \frac{2\pi}{24 \times 3600} = 7.27 \times 10^{-5} \text{ rad/s} \]

\[ L = I \omega = 7.15 \times 10^{33} \text{ kgm}^2 \]

b. In its orbit around the Sun (think of the earth as a single particle orbiting the Sun)

\[ L = 1mR^2 \]

\[ L = (6.7 \times 10^{24} \text{ kg})(1.5 \times 10^{11} \text{ m})^2 = 1.75 \times 10^{37} \text{ kgm}^2 \]

\[ \omega = \frac{2\pi}{365.24 \times 3600} = 1.99 \times 10^{-7} \text{ rad/s} \]

\[ L = I \omega = 7.1 \times 10^{40} \text{ kgm}^2 \]

7. When stars get close to the end of the life cycles, some stars can collapse to neutron stars which are INSANELY dense. Suppose you have a star about the same size as our sun (Rsun = 7*10⁵ km) that is rotating about its axis once every 10 days. It collapses down to a neutron star with a radius of 100 km. What is its new rotational speed? How fast is the outer edge of the star moving? (3.902 rpm, 128,000 km/hr)

\[ \omega_i = \frac{2\pi}{(10 \text{ days})(24 \text{ hr/day})} \]

\[ \omega_i = 6.94 \times 10^5 \text{ rpm} \]

\[ \omega_f = \omega_i \frac{r_f}{r_i} \]

\[ \omega_f = \frac{100}{7 \times 10^5} (6.94 \times 10^5) = 1.49 \times 10^3 \text{ rpm} \]

\[ \omega_f = 89.2 \text{ rpm} \]

\[ V = \omega_f r_f \]

\[ V = 89.2 \times 10^3 \text{ rpm} \times \frac{1}{60} \times 10^5 \text{ km} \]

\[ V = 128 \times 10^3 \text{ km/hr} \]

\[ V = 3902 \text{ km/hr} \]
